Subject: FORTRAN Implementation of Complex Least Squares Adaptive Lattice Algorithm as an All Zero Inverse Filter

References: See Pages 14 and 15.

ABSTRACT

A complex least squares adaptive lattice algorithm (1) has been implemented on the ARL VAX/VMS computer as an inverse all zero filter. A FORTRAN program package is presented which also includes a recursive realization of a pole-zero prefilter and an input signal generator. A series of examples is taken from the speech field, using the inverse filter to deconvolve speech signals produced by vocal tract models of varying complexity. The input to the prefilter is shown to be accurately recovered as the output of the inverse filter.

INTRODUCTION

A complex least squares lattice adaptive algorithm (1) has been implemented on the ARL VAX/VMS computer as an inverse all zero filter. An interactive FORTRAN program package is presented which also includes a recursive realization of a pole-zero prefilter and an input signal generator. No knowledge of FORTRAN is required to use the package. The input signal characteristics, filter coefficients and critical lattice parameters are all user specified.

Three classes of adaptive algorithms are treated in the literature: (Widrow's) LMS, the gradient lattice, and the least squares lattice. Of the three, the least squares adaptive lattice algorithm has been shown to have the fastest convergence rate (2,3). For this reason, it has been used successfully in a wide range of applications; i.e., data deconvolution, system identification, speech processing, and spectral whitening. The program package described in this memorandum was developed with these applications in mind.

BACKGROUND

Consider a filter with transfer function

$$H(z) = \frac{Z(z)}{V(z)} = \frac{B(z)}{A(z)} \quad (1)$$

where

$$A(z) = 1 + \sum_{k=1}^{NPOLE} A_k z^{-k} = \sum_{k=0}^{NPOLE} A_k z^{-k}, A_0 = 1$$

November 12, 1982
BAC-LHS :cac

and

$$B(z) = 1 + \sum_{k=1}^{NZERO} B_k z^{-k} = \sum_{k=0}^{NZERO} B_k z^{-k}, B_0 = 1$$

then $Z(z)A(z) = B(z)V(z)$ and, after taking inverse z transforms of both sides, the filter can be realized in the time domain by the following recursion:

$$z(n) + \sum_{k=1}^{NPOLE} A_k z(n-k) = v(n) + \sum_{k=1}^{NZERO} B_k v(n-k)$$

or

$$z(n) = - \sum_{k=1}^{NPOLE} A_k z(n-k) + v(n) + \sum_{k=1}^{NZERO} B_k v(n-k).$$

The roots of $A(z)$ are the poles of the system; the roots of $B(z)$ are the zeroes of the system. For stability, these roots must lie outside the unit circle because they are roots of polynomials in z^{-1} .

The resonances and antiresonances of the human vocal tract (for a particular steady state vowel sound) can be modeled by poles and zeroes, respectively, in the z plane. It is a common practice in the speech field to model these formants with an all pole model rather than with poles and zeroes; adding a sufficient number of poles has been shown to closely approximate the effect of the zeroes. The roots of the denominator polynomial are related to the vocal tract formants by the following expression (5):

$$z_k, z_k^* = z_{2k}, z_{2k-1} = e^{-\sigma_k T} e^{\pm j 2\pi F_k T}$$

November 12, 1982
BAC-LHS:cac

where F_k is the formant frequency and $2\sigma_k$ is the bandwidth of the k^{th} formant. There will be a pair of complex conjugate poles for each formant frequency; the order of the system will be twice the number of formants.

Then

$$H(z) = \frac{1}{\prod_{k=1}^{NPOLE} (1+z_k z^{-1})}.$$

For the all-pole model, the time domain recursion becomes

$$z(n) = -\sum_{k=1}^{NPOLE} A_k z(n-k) + v(n).$$

An inverse filter for the system of Equation 1 would have the transfer function

$$H(z) = \frac{A(z)}{B(z)}.$$

For the speech case (all-pole prefilter), the inverse filter would be all-zero:

$$H_{\text{pre}}(z) = \frac{1}{A(z)}; H_{\text{inv}}(z) = \frac{1}{H_{\text{pre}}(z)} = A(z).$$

Obviously, if the systems are cascaded, the input to the prefilter will be recovered as the output of the inverse filter.

A complex adaptive lattice structure has been used to develop the inverse filter. The actual lattice algorithm is taken from (1). Users are referred to (2) and (3) and the references cited therein for the derivations of the complex least squares adaptive lattice algorithm.

BAC-LHS:cac

PROGRAM PACKAGE

The lattice program package consists of the following interactive FORTRAN programs:

| | |
|------------|---|
| GEN.FOR | input generator |
| FILTER.FOR | prefilter and realization of the lattice filter |
| LSL.FOR | complex adaptive lattice processor |

the following subroutines:

| | |
|--------|---|
| SYNTH | synthesizes complex polynomial from formants and bandwidths |
| SYNTH1 | synthesizes complex polynomial from its roots |
| ZCPOLY | solves polynomial with complex coefficients |

and the following functions:

| | |
|-------------|---|
| MTH\$RANDOM | (VAX/VMS library) uniform random number generator |
| AMAXLOC | finds location of highest value in an array |
| ARRMAX | finds highest value in an array |

The execution of the programs may be controlled by either one of two command procedures: LATTICE.COM when using a VT100 terminal, or LATTEK.COM when using the Tektronix terminal in Room 358, ASB. These command procedures are given in Appendix A. They may be invoked by typing α LATTICE and β LATTEK, respectively. The following command should be placed into either the command procedure or the user's LOGIN.COM file to allow access to the IMSL package. If LNK\$LIBRARY has already been assigned, use LNK\$LIBRARY1 or the next highest unassigned library.

`$ASSIGN DRA0:[SYSTEM]IMSLIBS.OLB LNK$LIBRARY`

November 12, 1982
BAC-LHS:cac

Appendix B presents a sample terminal session for the case illustrated in Figure 3. For the user interested in modifying the programs, the rest of this memorandum deals with the structure of the individual programs.

Figure 7 illustrates the calling hierarchy of the lattice package. The inputs to program LSL are Gaussian white noise and the output time series $z(n)$ from program FILTER.FOR. The outputs from LSL are the set of inverse filter coefficients (A_k ; $k=1, \dots, NZERO$) to which the lattice has adapted after the requested number of iterations, and the time series output $e_p(n)$ which is equivalent to the result of passing the input time series $z(n)$ through the transfer function $H(z) = A(z)$. The output filter coefficients are fed back into program FILTER to be realized recursively with input $z(n)$. Thus, since program FILTER operates for any $H(z)$, it is both a prefilter and the realization of the lattice filter.

A sample case, then, may be illustrated by a series of five plots (Figures 3-6). The relationships between the plots are shown by the block diagram in Figure 2:

- (a) input time series
- (b) prefilter transfer function
- (c) output of the prefilter
- (d) lattice (inverse) filter transfer function
(realized by program FILTER)
- (e) output of the lattice filter

So that the filter outputs may be most easily evaluated, the filter outputs (c) and (e) for deterministic prefilter inputs are time series plots; for a stochastic input, the outputs (c) and (e) are power spectra. The time series plots (c) and (e) (from above) for the deterministic case are

November 12, 1982
BAC-LHS:cac

presented in Figures 3-6 for one period of the waveform after the time series has stabilized (or adapted). Again, the output of the lattice filter should approximate the input to the prefilter if the lattice is a true inverse filter. It is obvious that some measure of goodness of the inverse filter should be applied to the output of the lattice filter. At present, only a graphical comparison has been attempted. However, Gray and MarkeI (7) suggest a spectral flatness measure which will help to smooth the discontinuities in the power spectrum caused by the occurrence of the inverse filter zeroes being offset by a few Hz. from the prefilter poles. Also, a mean square error criterion might be applied to the difference between the deterministic time series output (error signal) and the input time series. The transfer function of the lattice filter should be the inverse of the prefilter transfer function. Thus, where the prefilter has poles (peaks) the inverse filter will have zeroes (dips).

GEN.FOR

Program GEN.FOR generates both Gaussian white noise and an impulse sequence. A more accurate approximation to the glottal wave is given in (7). However, since the thrust of this work is aimed at demonstrating that the lattice filter is indeed an accurate inverse filter, the two cases used so far are sufficient models of voiced and unvoiced steady state vocal tract excitations.

Program GEN.FOR calls the uniform random number generator, MTH\$RANDOM, from the VAX/VMS library. The Gaussian noise is then developed following a technique from (9). The output time series are in complex format but the imaginary parts are zero. The sampling frequency is 10 kHz. For

November 12, 1982
BAC-LHS:cac

the complex impulse input, the frequency is variable; the examples shown in Figures 3 and 5 use $F_0 = 125$ Hz, a reasonable fundamental frequency for an adult male voice. The interactive user inputs to program GEN are F_0 , fundamental frequency; M , number of desired samples; and σ , the standard deviation of the noise. The time series are each stored in an output disk file.

FILTER.FOR

The user selects the desired type of input and the source of the filter coefficients. Several options exist concerning specification of coefficients. The formant frequencies and their bandwidths may be specified and the coefficients calculated from subroutine SYNTN and then stored on disk. The stored coefficients may be used with another input option, reading in coefficients from disk. The coefficients may be typed in directly from the keyboard. For the realization of the lattice (inverse) filter, the forward predictor (outputs from program LSL) coefficients may be read in from disk as the lattice filter coefficients. The other interactive user inputs to FILTER.FOR are M , desired number of time samples; NPOLE, number of poles; and NZERO, the number of zeroes. It is possible to specify a prefilter transfer function which has both poles and zeroes (the inverse filter would still be all zero). The modeling of a pole zero process by an all-pole process is discussed by Friedlander and Maitra (6). The examples presented here involve prefilters containing only poles for the purpose of illustrating the accuracy of the all-zero inverse filter.

The filter gain is computed by the following formula:

$$G = 10 \log \frac{\sum_{n=1}^M z^2(n)}{\sum_{n=1}^M v^2(n)} = \frac{\sigma_z^2}{\sigma_v^2}$$

where $\omega = 0$ and $\sigma_z^2 = \sigma_v^2 = \sigma_x^2 + \sigma_y^2$.

The filter transfer function is realized from the filter coefficients by the following formula:

$$20 \log |H(\omega)| = 20 \log \left| \frac{1}{A(z)} \right| = 20 \log \left(\frac{1}{A(z) \cdot A^*(z)} \right)^{\frac{1}{2}}$$

for the prefilter and

$$20 \log |A(z)| = 20 \log (A(z) \cdot A^*(z))^{\frac{1}{2}}$$

for the lattice filter, where

$$A(z) = 1 + \sum_{k=1}^{NPOLE} A_k e^{-j\omega k}.$$

The frequency range of the plots is 0-5000 Hz.

The output power spectrum is computed (4) for the stochastic case from $10 \log P(\omega)$ where

$$P(\omega) = P_{in}(\omega) \cdot |H(\omega)|^2 = P_{in}(\omega) \cdot \frac{1}{A(z) \cdot A^*(z)}.$$

For the prefilter, $P_{in}(\omega) = \sigma_{in}^2 = \sigma_v^2$. For the lattice filter, $P_{in}(\omega)$ will be $P_{out}(\omega)$ from the prefilter, and $P(\omega) = P_{in}(\omega) \cdot |H(\omega)|^2 = P_{in}(\omega) \cdot A(z) \cdot A^*(z)$. Again, the frequency range of the plots is 0-5000 Hz.

November 12, 1982
BAC-LHS:cac

LSL.FOR

Figure 1 shows the structure of the least squares complex adaptive lattice. Table I lists the lattice parameters and their relationships to the text equations in (3) and to the FORTRAN code in (1). The algorithm from (1) has been modified (from RATFOR) for use by the ARL VAX/VMS computer. Users are referred to (2) for a detailed explanation of filter parameters. The interactive user inputs to program LSL are SNR, desired signal to noise ratio in dB; ALSL, value of α_{CLSL} ; P, order of the filter; and LIM, the desired number of iterations. After LIM number of iterations, the forward predictor coefficients become the filter coefficients of the inverse filter. The convergence properties of this lattice structure have been studied by Hodgkiss (2,3) and are not considered here. The maximum allowable number of iterations is set at 5000 which allows the lattice more than enough time to adapt.

Subroutine ZCPOLY solves the filter polynomial to make sure the roots are outside the unit circle. If a root is inside the unit circle, it is inverted and a new polynomial is synthesized with subroutine SYNTH1. The coefficients are then stored on disk for use by program FILTER.

The forward and backward reflection (PARCOR) coefficients are also stored on disk for possible future use. These parameters are related to the reflection coefficients of an acoustic tube model of the vocal tract. The next step in this research effort will involve making use of these coefficients to directly identify the prefilter transfer function. Table II lists the prefilter coefficients, final lattice coefficients, and both sets of final PARCOR coefficients for the four sample cases presented in Figures 3-6.

November 12, 1982
BAC-LHS:cac

The desired signal to noise ratio is achieved by scaling down the added noise (of user specified standard deviation from GEN.FOR) rather than scaling up the signal. This is accomplished by solving for the desired σ of the noise (8):

$$\text{SNR} = 10 \log \frac{\lim_{n=1}^{\infty} \text{sig}^2(n)}{\lim_{n=1}^{\infty} \text{noise}^2(n)}$$

taking the antilog:

$$10^{(\text{SNR}/10)} = \frac{\lim_{n=1}^{\infty} \text{sig}^2(n)}{\lim_{n=1}^{\infty} \text{noise}^2(n)}$$

$$\lim_{n=1}^{\infty} \text{noise}^2(n) = \frac{1}{10^{(\text{SNR}/10)}} \lim_{n=1}^{\infty} \text{sig}^2(n)$$

$$\frac{\lim_{n=1}^{\infty} \text{noise}^2(n)}{\lim_{n=1}^{\infty}} = \sigma_{\text{noise}}^2 = \frac{\lim_{n=1}^{\infty} \text{sig}^2(n)}{\lim_{n=1}^{\infty} 10^{(\text{SNR}/10)}}$$

$$\sigma_{\text{noise}} = \left(\frac{\lim_{n=1}^{\infty} \text{sig}^2(n)}{\lim_{n=1}^{\infty} 10^{(\text{SNR}/10)}} \right)^{\frac{1}{2}}$$

Therefore, multiply the noise samples by the factor $\frac{\sigma_{\text{noise}}}{\sigma_{\text{input}}}$.

TABLE II

FORMANT FREQUENCIES, THEIR BANDWIDTHS, AND CORRESPONDING
FILTER COEFFICIENTS FOR THE FOUR INPUT CASES DEPICTED IN FIGS. 3-6

APPENDIX
FORTRAN SOURCE

Command Procedure LATTICE.COM
Controls Sequence of Program Execution for VT100 Terminals

RECORDED AND INDEXED IN THE CLERK'S OFFICE OF THE COUNTY OF SANTA BARBARA, CALIFORNIA, ON THE 12TH DAY OF APRIL, 1907. THIS IS THE FIRST SIGNED COPY.
BY JAMES H. COOPER, CLERK OF THE COURT.

WHICH WAY WILL COME THE DECISIONS AT ANY TIME BY TAKING AN AFTER THE PHASE TO
COMMITTEE. WHICH WILL BE ABLE TO GATHER WORDS OF DATA FILES WITHIN THE
CORPORATE STRUCTURE, WHICH WILL EXAMINE THE PHASES AND ANALYZE DATA FILES
TO IDENTIFY CHANGES IN STATE. IT SHALL THEN AUTOMATICALLY MATCH PHASES WHICH

TO RECENT. & THE NAME OF FLOCK NUMBER WHICH LIKES TO DINE,
SELECTED FENCE, & PLACES WHICH THE CLOTH TYPE. FOR EXAMPLE, ST. LEEPS, MGR FILTER, FOR
WANTED YOU SHOULD PROVIDED WITH A LIST ON THE SCREEN, PRESS THE SPACE BAR TO
MOVE THE CURSOR TO CHOOSE AND THE NEXT BELL TO APPAREL.

TO USE THE PATTERN BUTTON, PRESS THE PATTERN BUTT

THESE ARE THE FIRST IN THE SERIES.

PLEASE GIVE US A CHANCE TO PROVE OURSELF.

Command Procedure LATTEK.COM Controls Sequence of Program Execution for Tektronix Terminal

***** IN STAR SCHOOL, WHICH IS OWN PROPERTY. THE STAFF ARE ALL THOSE WHO SCHOLARSHIP
***** LEARNED AND SKILLED WORKERS. THE TEACHERS ARE ALL THOSE WHO HAVE BEEN
***** PREPARED FOR TEACHING BY PRACTICAL EXPERIENCE. THE STUDENTS ARE ALL THOSE WHO
***** ARE LEARNING AND ARE BEING PREPARED FOR FUTURE USE.

you can always edit, move, or delete the documents at any time by typing `vi` after the prompt.

THE LITERATURE OF THE PRACTICAL ARTS.

Program GEN. FOR

C TULI MUNICIPAL HAS BEEN DETERMINED AS OF 12/16/87. THE LISTINGS SUPPLIED
C WITH API THIS DATE, VENUE NUMBER #2-214, DATED 11/12/82 ARE NO LONGER
C CURRENT. PLEASE NOTIFY NEW LISTERS.

For further details contact CIPR WITH APPROPRIATE INSTRUCTION.

C 100117 زدنیکویلر فریم راکداتور

Cubic B-spline generates complex Gaussian noise with variable standard deviation and directly found to significant for VANTAHIE printing.

Program LSL FOR Least Squares Complex Lattice Processor

THIS RANGERS WAS CHECKED OVERSIGHT AS OF 17/6/82. THE LISTINGS SUPPLIED WITH ALL INFORMATION UPDATING 4/2/81, DATED 11/17/82 ARE NOT ENOUGH CURRENT.
DISEASE CONTAIN A NEW LISTING.

LET ALONE, IT'S SO DARNED EASY TO DO THEM
TYPE OF PERSON I DON'T KNOW. THEY AGAIN,
GOD BLESS YOU.

THE SECRET INSTITUTIONS OF THE NFAC, MINUTEMEN, & C. S. A.

PHOTOGRAPHIC EQUIPMENT AND USEFUL INFORMATION FOR THE FIELD.

SECTION FOURTH - STRUCTURE.

如上所述，本章所讨论的“政治”是广义的，即指一切政治性事件。

TYPE 0, S FIELD F11.7+0 NUMBER ($\epsilon = \mu <= (\kappa)$)
 ACCEPT 0, 1
 IF $\epsilon < 0.1$ THEN

WOLFE (1981, 1983) has
shown that the mean annual
energy fluxes from the sun and
the earth are constant over time.
However, the energy fluxes from
the sun and the earth are not
constant over time. The sun's
energy flux is constant over time,
but the earth's energy flux is not.
The earth's energy flux is
constant over time, but the sun's
energy flux is not.

$\rho_0 > \rho_{n-1} = \rho_{n+1}$
 $\Gamma_{\rho} = 10^{-1} \Gamma_{\rho+2}$
 $F(\Gamma_{\rho}, \beta) = (\rho_{\rho}, \rho_{\rho})$
 $A(\Gamma_{\rho}, \beta) = (\rho_{\rho}, \rho_{\rho})$
 $B(\Gamma_{\rho}, \beta) = (\rho_{\rho}, \rho_{\rho})$
 $C(\Gamma_{\rho}, \beta) = \rho_{\rho}$

THE PREDICTIVE ACCURACY OF THE STAPLE INDEX FOR PREDICTION OF THE AVIAN INFLUENZA RISK

The fourth figure is executed end each time sample. The first figure characterizes initial state of the lattice. The second figure shows the evolution of the lattice after 7 time steps.

ASIN IS A NUMBER OF THE PRODUCT DESCRIPTION CATEGORIES.
PICK THE ONE(S) OF THE CATEGORIES.
27 (OPTIONAL) FOR ACTIVATION OF THE CIRCLE AT THIS POSITION THAT THE 200-1.
IS IN A POSITION (T/F).

THE JOURNAL OF CLIMATE VOL. 14, NO. 10, OCTOBER 2001

卷之三

卷之三

These documents tell fitted relationships between the amount of time spent in the library and the amount of time spent in the library. The books in this library are in 7000+.

1920-21 und 1921-22 der 1. Klasse der Universität Bonn und 1922-23 der 2. Klasse der Universität Berlin.

THESE ARE THE CHIEF CONCEPTS WHICH ARE USED IN THIS STUDY TO CLASSIFY

卷之三

SUBROUTINE SYNTH(N,FF,BW,HR,CC,FSS)

THIS SUBROUTINE SYNTHESIZES A COMPLEX POLYNOMIAL IN Z^{N-1} FROM AN ARRAY OF THE ROOTS OF THE POLYNOMIAL.

N IS THE ORDER OF THE POLYNOMIAL.

FF (INPUT) IS AN ARRAY OF THE FILTER COEFFICIENTS OF THE POLYNOMIAL IN Z^{N-1} .

```

SUBROUTINE SYNTH(N,FF,BW,HR,CC,FSS)

 THIS SUBROUTINE SYNTHESIZES A COMPLEX POLYNOMIAL IN Z^{N-1} FROM AN ARRAY OF FOMANT FREQUENCIES AND AN ARRAY OF THEIR RESPECTIVE BANDWIDTHS.

 C THIS PROGRAM HAS BEEN REVISED AS OF 1/24/83. THE LISTINGS SUPPLIED
 C WITH ARE INTERNAL FOR RAINUN R2-219, DATED 11/12/82 ARE NO LONGER
 C CORRECT. PLEASE OBTAIN NEW LISTINGS.

```

C THIS SUBROUTINE SYNTHSIZES A COMPLEX POLYNOMIAL IN  $Z^{N-1}$  FROM AN  

C ARRAY OF FOMANT FREQUENCIES AND AN ARRAY OF THEIR RESPECTIVE BANDWIDTHS.  

C N IS THE NUMBER OF FOMANTS AND THE DEGREE OF THE POLYNOMIAL.  

C FF IS AN ARRAY OF THE FOMANT FREQUENCIES IN Hz.  

C BW IS AN ARRAY OF THEIR BANDWIDTHS IN Hz.  

C HR IS AN ARRAY OF THE REAL PARTS OF THE FILTER COEFFICIENTS.  

C RR (INPUT) IS AN ARRAY OF THE REAL PARTS OF THE FILTER COEFFICIENTS.  

C CC (OUTPUT) IS AN ARRAY OF THE IMAGINARY PARTS OF THE FILTER COEFFICIENTS.  

C SFF TEXT FOR RELATIONSHIPS BETWEEN FORWARD, THEIR BANDWIDTHS,  

C AND THE FILTER COEFFICIENTS.
```

SIGHTING & DRAUGHTS OF THE CLOUDS, ETC., ON NOV. 10.
 SWELLING PICTURED IN GREEN, WHICH IS DRAWN WASHED ON EACH 314
 ELEVEN INCHES AT FORT 7, LIGHTEST BROWN & HIGHLIGHT
 IS SPOTTED, OR SPOTTED = 1.

SPOTTED IS THE SPOT ON A HIGHLIGHT DRAWN SPOTTED SPOTTED, AND
 SPOTTED IS A SPOTTED SPOT. EACH SPOTTED INDIVIDUALLY AS A VAWAH, IF
 IN THE PAINTING CONSIDERED AS ONE WHOLE, UNQUOTE THE SIXTH VALUE.
 (INTERESTING POINT OF REFLACED CLOUDS IN THE CLOUDING UNIT ONE).

| | | |
|--------------|--|-------------------|
| LUN | $\text{Y} = 2.00 \times 10^{-4} (\text{GREEN})$ | $= 1.0$ |
| Y | $= 2.00 \times 10^{-4} (\text{GREEN})$ | $= 1.0$ |
| C | $= 1.002 + 0.007$ | |
| Lc | $(\text{S} - 0.002) \times 10^{-4}$ | $\text{S} = 1.00$ |
| Q | $= \text{S} - 0.002 \times 10^{-4} (\text{GREEN})$ | |
| C | $= 1.00$ | |
| Lc | $= 0.998$ | |
| C | $= 0.998$ | |
